

SIH Winners: Visual & Presentation Research

Examples

1. Cryptonite / PhishTrap: Team Cryptonite from MIT Manipal worked on an AI-based anti-phishing solution. Instead of only showing the AI part, they had a proper product around it, including a browser extension/app idea. The main point was real-time protection, so the technical part had an actual use behind it.

2. Hacktivists_24: Their project was about identifying people involved in drug trafficking through social media. They collected and filtered account information, analysed it using ML and multimodal analysis, and then put the useful results into a dashboard for NCB officials. So there were quite a few technical layers, but they also had a proper way of showing the final results.

3. Enigmaa: This team worked on AI/ML-based optimisation for railway rake planning. What stood out here was that the system was not just giving some prediction — it was helping with an actual planning decision. The technical optimisation could then be represented through the final plan or recommendation given by the system.

What I noticed

- These projects weren't really simple technically. Most of them had multiple parts working together, like data collection, analysis, AI/ML and then some final output.
- The technical side actually seemed to add to the project because it was connected to what the problem needed.
- The visual part helped in showing what all that technical work was finally producing.
- Dashboards and interfaces were useful because they gave the technical output somewhere practical to go.

What we can take from this

- I think having a strong technical side can actually help our project stand out, as long as we can clearly show why we're using it and how it improves the solution.
- We just need to be able to explain why we used each major technology and what it is doing in the project.
- Things like our architecture, AI/ML, algorithms, data flow and integrations can be shown properly during the presentation to highlight the technical side of our work.
- Basically, we can have a strong and complex system behind the project while still making the demo easy enough for the judges to follow.

My conclusion: What I got from these examples is that technical depth is not a bad thing at all. It can actually make a project more impressive. We just need to make sure the technical parts are there for a reason and that we can explain and demonstrate them properly.
